# Capítulo 1

# Introdução

### 1.1 Template

Digitar o template no inicio da prova. NÃO esquecer de remover o freopen()

```
#include <bits/stdc++.h>
using namespace std;
#define all(v) (v).begin(), (v).end()
#define pb push_back
#define fst first
#define snd second
#define debug(x) cout << #x << "_=_" << x << endl;
typedef pair <int , int > ii;
int main() {
    freopen("in", "rt", stdin);
    return 0;
}
typedef long long ll;
```

### 1.2 Fast Input

Em casos extremos mete isso sem medo.

# 1.3 Bugs do Milênio

Cortesia da ITA.

#### Erros teóricos:

- Não ler o enunciado do problema com calma.
- Assumir algum fato sobre a solução na pressa.
- Não reler os limites do problema antes de submeter.
- Quando adaptar um algoritmo, atentar para todos os detalhes da estrutura do algoritmo, se devem (ou não) ser modificados (ex:marcação de vértices/estados).
- O problema pode ser NP, disfarçado ou mesmo sem limites especificados. Nesse caso a solução é bronca mesmo. Não é hora de tentar ganhar o prêmio nobel.

#### Erros com valor máximo de variável:

- Verificar com calma (fazer as contas direito) para ver se o infinito é tão infinito quanto parece.
- Verificar se operações com infinito estouram 31 bits.
- Usar multiplicação de *int*'s e estourar 32 bits (por exemplo, checar sinais usando a \* b > 0).

#### Erros de casos extremos:

- Testou caso n=0? n=1? n=MAXN? Muitas vezes tem que tratar separado.
- Pense em todos os casos que podem ser considerados casos extremos ou casos isolados.

- Casos extremos podem atrapalhar não só no algoritmo, mas em coisas como construir alguma estrutura (ex: lista de adj em grafos).
- Não esquecer de self-loops ou multiarestas em grafos.
- Em problemas de caminho Euleriano, verificar se o grafo é conexo.

#### Erros de desatenção em implementação:

- Errar ctrl-C/ctrl-V em código. Muito comum.
- Colocar igualdade dentro de if? (if(a = 0)continue;)
- Esquecer de inicializar variável.
- Trocar break por continue (ou vice-versa).
- Declarar variável global e variável local com mesmo nome (é pedir pra dar merda...).

#### Erros de implementação:

- Definir variável com tipo errado (int por double, int por char).
- Não usar variável com nome max e min.
- Não esquecer que .size() é unsigned.
- Lembrar que 1 é int, ou seja, se fizer  $long \ long \ a = 1 << 40$ ;, não irá funcionar (o ideal é fazer  $long \ long \ a = 1LL << 40$ ;).

#### Erros em limites:

- Qual o ordem do tempo e memória? 10<sup>8</sup> é uma referência para tempo. Sempre verificar rapidamente a memória, apesar de que o limite costuma ser bem grande.
- A constante pode ser muito diminuída com um algoritmo melhor (ex: húngaro no lugar de fluxo) ou com operações mais rápidas (ex: divisões são lentas, bitwise é rápido)?

# 1.4 Recomendações gerais

Cortesia da PUC-RJ.

#### ANTES DA PROVA

- Revisar os algoritmos disponíveis na biblioteca.
- Revisar a referência STL.
- Reler este roteiro.
- Ouvir o discurso motivacional do técnico.

#### ANTES DE IMPLEMENTAR UM PROBLEMA

- Quem for implementar deve relê-lo antes.
- Peça todas as clarifications que forem necessárias.
- Marque as restrições e faça contas com os limites da entrada.
- Teste o algoritmo no papel e convença outra pessoa de que ele funciona.
- Planeje a resolução para os problemas grandes: a equipe se junta para definir as estruturas de dados, mas cada pessoa escreve uma função.

• O exercício é um caso particular que pode (e está precisando) ser otimizado e não usar direto a biblioteca?

#### Erros em doubles:

- Primeiro, evitar (a não ser que seja necessário ou mais simples a solução) usar float/double. E.g. conta que só precisa de 2 casas decimais pode ser feita com inteiro e depois %100.
- Sempre usar *double*, não *float* (a não ser que o enunciado peça explicitamente).
- Testar igualdade com tolerância (absoluta, e talvez relativa).
- Cuidado com erros de imprecisão, em particular evitar ao máximo subtrair dois números praticamente iguais.

#### Outros erros:

- Evitar (a não ser que seja necessário) alocação dinâmica de memória.
- Não usar STL desnecessariamente (ex: vector quando um array normal dá na mesma), mas usar se facilitar (ex: nomes associados a vértices de um grafo map < string, int >) ou se precisar (ex: um algoritmo O(nlogn) que usa < set > é necessário para passar no tempo).
- Não inicializar variável a cada teste (zerou vetores? zerou variável que soma algo? zerou com zero? era pra zerar com zero, com -1 ou com INF?).
- Saída está formatada corretamente?
- Declarou vetor com tamanho suficiente?
- Cuidado ao tirar o módulo de número negativo. Ex.: x%n não dá o resultado esperado se x é negativo, fazer (x%n+n)%n.

#### DEBUGAR UM PROGRAMA

- Ao encontrar um bug, escreva um caso de teste que o dispare.
- Reimplementar trechos de programas entendidos errados.
- $\bullet$  Em caso de RE, procure todos os [, / e %.

### 1.5 Os 1010 mandamentos

Também cortesia da PUC-RJ.

- 0. Não dividirás por zero.
- 1. Não alocarás dinamicamente.
- 2. Compararás números de ponto flutuante usando EPS.
- 3. Verificarás se o grafo pode ser desconexo.
- 4. Verificarás se as arestas do grafo podem ter peso negativo.
- 5. Verificarás se pode haver mais de uma aresta ligando dois vértices.
- 6. Conferirás todos os índices de uma programação dinâmica.
- 7. Reduzirás o branching factor da DFS.
- 8. Farás todos os cortes possíveis em uma DFS.
- 9. Tomarás cuidado com pontos coincidentes e com pontos colineares.

# 1.6 Limites da representação de dados

tipo	bits	mínimo	 máximo	precisão decimal
char	8	0	 127	2
signed char	8	-128	 127	2

# Capítulo 2

# Estruturas de dados

#### 2.1 Prefix Sum 1D

```
Soma a..b em O(1).

#define MAXN 1000
int arr [MAXN];
int prefix [MAXN];

void build (int n) {
    prefix [0] = 0;
    for (int i = 1; i <= n; i++) // arr 1-indexado
}

prefix [i] = prefix [i-1]+arr[i];

int get (int a, int b) {
    return prefix [b] - prefix [a-1];
}
</pre>
```

### 2.2 Prefix Sum 2D

```
Soma um subretângulo em ponto em O(1).
Indexado em 1.

#define MAXN 1000
int mat [MAXN] [MAXN], prefix [MAXN] [MAXN];

void build(){
   for (int i = 1; i <= n; i++)
        for (int j = 1; j <= n; j++)
            prefix[i][j] = mat[i][j] + prefix[i - 1][j] + prefix[i][j - 1] - prefix[i - 1][j - 1];
}

int get(int x1, int y1, int x2, int y2){
   return prefix[x2][y2] - prefix[x1 - 1][y2] - prefix[x2][y1 - 1] + prefix[x1 - 1][y1 - 1];
}</pre>
```

#### 2.3 BIT - Fenwick Tree

```
Soma 1..N e update em ponto em O(log n).
```

```
#define MAXN 10000
int bit [MAXN];

void update(int x, int val){
    for(; x < MAXN; x+=x&-x)
        bit [x] += val;
}

int get(int x) {
    int ans = 0;
    for(; x; x-=x&-x)
        ans += bit [x];
    return ans;
}
```

## 2.4 BIT - Fenwick Tree - Range updates

Consulta em range e update em range (v[i..j]+=v) em O(logn).

```
vector < int > bit1, bit2;
                                                                                                       \begin{tabular}{lll} \bf void & \tt update(int i, int j, int v) \\ \end{tabular} 
void init(int n){
                                                                                                            up\,dat\,e\,(\,b\,i\,t\,1\ ,\ i\ ,\ v\,)\;;
      b\,i\,t\,1\,\,.\,\,a\,s\,s\,i\,g\,n\,\,(\,n\,+\,1\,,\quad 0\,)\,\,;
                                                                                                            \begin{array}{l} {\rm update}\,(\,{\rm bit}\,1\ ,\ j+1,\ -v\,)\,;\\ {\rm update}\,(\,{\rm bit}\,2\ ,\ i\ ,\ v*(\,i-1)\,)\,; \end{array}
      bit 2. assign (n+1, 0);
                                                                                                            update(bit2, j+1, -v*j);
int rsq(vector < int > \&bit, int i){
      int ans = 0;
       {\bf for} \; (\; ; \quad i \; ; \quad i \! - \! \! = \! i \& \! \! - \! i \; ) \\
                                                                                                      int rsq(int i){
          ans += bit[i];
                                                                                                            return rsq(bit1, i)*i - rsq(bit2, i);
      return ans:
                                                                                                      \mathbf{int} \ \operatorname{rsq} \left( \ \mathbf{int} \ \ \mathrm{i} \ , \ \ \mathbf{int} \ \ \mathrm{j} \ \right) \{
{f void} update(vector<{f int}> &bit, {f int} i, {f int} v){
                                                                                                           return rsq(j) - rsq(i-1);
      for(; i < bit.size(); i+=i&-i)
           bit [i] += v;
```

#### 2.5 BIT - Fenwick Tree 2D

Soma um subretângulo e update em ponto em  $O(log^2n)$ .

```
#define MAXN 1000
int bit [MAXN] [MAXN];

void update(int x, int y, int val) {
    for (; x < MAXN; x+=x&-x)
        for(int j = y; j; j-=j&-j)
            ans += bit [x][j];

return ans;
}

for (int j = y; j < MAXN; j+=j&-j)
            bit [x][j] += val;
}

int get(int x, int y) {
    int get(int x, int y) {
        int get(x2, y2) - get(x1-1, y2) - get(x2, y1)
            -1) + get(x1-1, y1-1);
}
</pre>
```

## 2.6 BIT - Fenwick Tree 2D - Range Update

Update em range, consulta em ponto e em range.

```
\#define MAXN 505
                                                                            update(1, x1, y2+1, val*y2);
                                                                            update(1, x2+1, y1, val*(y1-1));
11 bit [4][MAXN + 50][MAXN + 50];
                                                                            update(1, x2+1, y2+1, -val*y2);

```

## 3.3 Convex hull trick 3 - Fully Dynamic

Sem condições especiais para o A e B

```
const ll is query = -(1LL << 62);
struct Line {
    ll m, b;
    mutable function < const Line * () > succ;
    bool operator < (const Line& rhs) const {
         \label{eq:final_continuous_continuous} \textbf{if} \ \ (\texttt{rhs.b} \ != \ \texttt{is\_query}) \ \ \textbf{return} \ \texttt{m} < \ \texttt{rhs.m};
         const Line* s = succ();
         if (!s) return 0;
         ll x = rhs.m;
        return b - s -> b < (s -> m - m) * x;
    }
};
struct HullDynamic : public multiset <Line> { //
      will \ maintain \ upper \ hull \ for \ maximum
    bool bad(iterator y) {
         \mathbf{auto} \ z \ = \ n \operatorname{ext} \left( \, y \, \right) \, ;
         if (y == begin()) 
             if (z == end()) return 0;
             return y->m == z->m \&\& y->b <= z->b;
         \mathbf{auto} \ \mathbf{x} = \mathbf{prev}(\mathbf{y});
```

```
if (z == end()) return y->m == x->m && y->b
           <= x->b;
      return (x->b - y->b)*(z->m - y->m) >= (y->b)
           - z -> b) *(y -> m - x -> m);
   void insert_line(ll m, ll b) {
    auto y = insert({ m, b });
      y \rightarrow succ = [=] { return next(y) == end() ? 0}
           : &*next(y); };
      if (bad(y)) { erase(y); return; }
      while (next(y) != end() \&\& bad(next(y)))
           erase(next(y));
      while (y != begin() && bad(prev(y))) erase(
           prev(y);
   ll eval(ll x) {
      auto l = *lower_bound((Line) { x, is_query
      return l.m * x + l.b;
};
```

## 3.4 Divide and conquer optimization

Dividir elementos em K pilhas sai de  $O(KN^2)$  para O(KNlogN).

```
void solve(int i, int left, int right, int kleft,
    int kright){
    if(left > right)
    return;

int jmid = (right+left)/2;
    dp[i][jmid] = 1 << 30;
    int best k = -1;
    for(int k = kleft; k <= min(kright, jmid); k++)
        {
        if(dp[i-1][k] + get(k+1, jmid) < dp[i][jmid
            ]) {
            dp[i][jmid] = dp[i-1][k] + get(k+1, jmid)
            ; // Cost function</pre>
```

```
bestk = k;
}
}
solve(i, left, jmid-1, kleft, bestk);
solve(i, jmid+1, right, bestk, kright);
}

// Chamada fica assim
for(int i = 1; i <= n; i++) // Casos base
dp[1][i] = get(1, i);

for(int i = 2; i <= k; i++)
solve(i, 1, n, 1, n);</pre>
```

# 3.5 Knuth optimization

Dividir elementos P elementos em A pilhas.

## 3.6 Otimização com bitmask

dp[i] é igual a um bitmask onde o i-ésimo bit informa se é possível fazer a soma i usando x elementos, onde x é a posição do bitmask.

```
dp[0] = 1;
for(int i = 0; i < n; i++)
  for(int j = sum/2; j >= v[i]; j--)
    dp[j] |= dp[j-v[i]] << 1LL;

int ans = sum/2;
if(n&1){
    ll x = 1LL << (n/2);</pre>
```

```
ll y = 1LL<<(n/2+1);
while (!(dp[ans]&x) && !(dp[ans]&y))
          ans--;
}
else
while (!(dp[ans]&(1LL<<(n/2))))
          ans--;</pre>
```

# Capítulo 4

# Grafos

# 5.2 Fórmula de Legendre

Dados um inteiro n e um primo p, calcula o expoente da maior potência de p que divide n! em O(log n).

```
11 legendre(ll n, ll p){
    ll ans = 0;
    ll prod = p;
    while(prod <= n) {
        ans += n/prod;
    }
    prod *= p;
    return ans;
}</pre>
```

## 5.3 Número de fatores primos de N!

Dado um N encontra quantos fatores o N! possui

```
// Sieve of Eratosthenes to mark all prime number
// in array prime as 1
void sieve(int n, bool prime[])
{
    // Initialize all numbers as prime
    for (int i=1; i<=n; i++)
    prime[i] = 1;

    // Mark composites
    prime[1] = 0;
}
</pre>
for (int i=2; i*i<=n; i++)
{
    for (int j=i*i; j<=n; j += i)
        prime[j] = 0;
}

}
```

```
// Returns the highest exponent of p in n!
int expFactor(int n, int p)
{
   int x = p;
   int exponent = 0;
   while ((n/x) > 0)
   {
      exponent += n/x;
      x *= p;
   }
   return exponent;
}

// Returns the no of factors in n!
countFactors(int n)
{
    // ans stores the no of factors in n!
```

```
11 ans = 1;

// Find all primes upto n
bool prime[n+1];
sieve(n, prime);

// Multiply exponent (of primes) added with 1
for (int p=1; p<=n; p++)
{
    // if p is a prime then p is also a
    // prime factor of n!
    if (prime[p]==1)
    ans *= (expFactor(n, p) + 1);
}

return ans;
}</pre>
```

### 5.4 Trailing zeros in factorial

```
int findTrailingZeros(int n) {
    // Initialize result
    int count = 0;

// Keep dividing n by powers of 5 and update
        count
```

#### 5.5 Número de divisores de N!

Dado um N encontra quantos divisores o N! possui

```
// all Primes[] stores all prime numbers less
// than or equal to n.
vector < ull > allPrimes;
// Fills above vector all Primes [] for a given n
void sieve(int n)
   // Create a boolean array "prime [0..n]" and
   // initialize all entries it as true. A value
   // in prime[i] will finally be false if i is // not a prime, else true.
   vector < bool > prime(n+1, true);
   // Loop to update prime[]
   for (int p=2; p*p \le n; p++)
      // If prime[p] is not changed, then it // is a prime
      if (prime[p] == true)
      {
          // Update all multiples of p
          for (int i=p*2; i \le n; i += p)
         prime[i] = false;
      }
   }
   // Store primes in the vector allPrimes
   for (int p=2; p \le n; p++)
   if (prime[p])
   allPrimes.push back(p);
}
```

```
// Function to find all result of factorial number
ull factorialDivisors(ull n)
   sieve(n); // create sieve
   // Initialize result
   ull result = 1;
   // find exponents of all primes which divides n
   // and less than n
    \label{eq:formula} \textbf{for (int} \quad i=0; \quad i \ < \ \texttt{allPrimes.size()}; \quad i++) 
       // Current divisor
      ull p = all Primes[i];
         Find the highest power (stored in exp),
      // of allPrimes[i] that divides n using
      // Legendre's formula.
      ull exp = 0;
       \mathbf{while} \ (p \le n)
          \exp = \exp + (n/p);
          p = p*allPrimes[i];
       // Multiply exponents of all primes less
       // than n
       result = result *(exp+1);
   // return total divisors
   return result;
```

## 5.6 Grundy Number

Faz o xor de todos os números grundy de todas as pilhas, se for diferente de 0 ganha o jogo.

```
if(x perde jogo)
    return 0;

ll ans = 0;
    while(st.count(ans)) ans++;
    return ans;
}

unordered_set<ll> st;
for(int i = 0; i < l; i++)
    st.insert(grundy(novoX)); // Transicoes
    return mex(st);
}</pre>
```

### 5.7 Baby-Step Giant-Step para Logaritmo Discreto

Resolve a equação  $a^x = b(modm)$  em O(sqrt(m)logm). Retorna -1 se não há solução.

```
template <typename T>
T baby (T a, T b, T m) {
                                                                                                      \label{eq:for_to_sign} \begin{array}{lll} \mbox{for} & (T & i = 0 \,, & c\,u\,r = b \,; & i < = n \;; & + + i \,\,) \end{array} \left. \right. \left. \left. \left\{ \right. \right. \right. \right.
                                                                                                            if (vals.count(cur)) {
     a %= m; b %= m;
     T\ n = \ (T)\ sqrt\ (m + \ .0)\ + \ 1;
                                                                                                                 T ans = vals[cur] * n - i;

#### 5.9Números de Catalan

Computa os números de Catalan de 0 até n em (nlogn). Olhar mais exemplos no CP3 pg. 206

- $Cat(n) = \text{número de árvores binárias completas de } n+1 \text{ folhas ou } 2^*n+1 \text{ elementos}$
- Cat(n) = número de combinações válidas para n pares de parêntesis.
- Cat(n) = número de formas que o parentesiação de <math>n+1 elementos pode ser feito.
- Cat(n) = número de triangulações de um polígono convexo de n+2 lados.
- Cat(n) = número de caminhos monotônicos discretos para ir de (0,0) a (n,n).

```
 \begin{array}{c} g \, = \, \gcd \left( 2 * (2 * i - 1) \, , \, \, i + 1 \right) \, ; \\ cat \, [\, i \, ] \, = \, \left( (\, 2 * (\, 2 * i - 1)\,) \, / \, g \, \right) * (\, cat \, [\, i \, - 1\,] \, / \, ((\, i + 1) \, / \, g) \\ ) \, ; \\ \} \\ \end{array} \right) \\ \end{array} 
ll cat [MAXN];
void catalan(int n){
        cat[0] = cat[1] = 1;
         ll g;
        for(int i = 2; i \le n; i++){
```

#### 5.10Fórmulas úteis

Olhar mais fórmulas no CP3 pg. 345

- Soma dos n primeiros fibonacci: f(n+2) 1.
- Soma dos n primeiros fibonacci ao quadrado: f(n) \* f(n+1).
- Soma dos quadrados de todos números de 1 até n: n\*(n+1)\*(2n+1)/6.
- Fórmula de Cayley: existem  $n^{n-2}$  árvores geradoras em um grafo completo de n vértices.
- Desarranjo: o número der(n) de permutações de n elementos em que nenhum dos elementos fica na posição original é dado por: der(n) = (n-1)(der(n-1) + der(n-2)), onde der(0) = 1 e der(1) = 0.
- Teorema de Erdos Gallai: é condição suficiente para que uma array represente os graus dos vértices de um nó:  $d_1 \geq d_2 \geq ... \geq d_n, \; \sum_{i=1}^n d_i = 2k, \; \sum_{i=1}^k d_i \leq k(k-1) + \sum_{i=k+1}^k \min(d_i,k).$
- Fórmula de Euler para grafos planares: V E + F = 2, onde F é o número de faces.
- ullet Círculo de Moser: o número de peças em que um círculo pode ser divido por cordas ligadas a n pontos tais que não se tem 3 cordas internamente concorrentes é dada por:  $g(n) = C_4^n + C_2^n + 1$ .
- ullet Teorema de Pick: se I é o número de pontos inteiros dentro de um polígono, A a área do polígono e b o número de pontos inteiros na borda, então A = i + b/2 - 1.
- O número de árvores geradores em um grafo bipartido completo é  $m^{n-1} \times n^{m-1}$ .
- Teorema de Kirchhoff: o número de árvores geradoras em um grafo é igual ao cofator da sua matriz laplaciana L. L = D - A, em que D é uma matriz diagonal em que  $a_{ii} = d_i$  e A é a matriz de adjacência.
- Teorema de Konig: a cobertura mínima de vértices em um grafo bipartido (o número mínimo de vértices a serem removidos para se remover todas as arestas) é igual ao pareamento máximo do grafo.
- Teorema de Zeckendorf: qualquer inteiro positivo pode ser representado pela soma de números de Fibonacci que não inclua dois números consecutivos. Para achar essa soma, usar o algoritmo guloso, sempre procurando o maior número de fibonacci menor que o número.
- Teorema de Dilworth: em um DAG que representa um conjunto parcialmente ordenado, uma cadeia é um subconjunto de vértices tais que todos os pares dentro dele são comparáveis; uma anti-cadeia é um subconjunto tal que todos os pares de vértices dele são não comparáveis. O teorema afirma que a partição mínima em cadeias é igual ao comprimenton da maior anti-cadeia. Para computar, criar um grafo bipartido: para cada vértice x, duplicar para  $u_x$  e  $v_x$ . Uma aresta  $x \to y$  é escrita como  $u_x \to v_y$ . O tamanho da partição mínima, também chamada de largura do conjunto, é N- o emparelhamento máximo.
- Teorema de Mirsky: semelhante ao teorema de Dilworth, o tamanho da partição mínima em anti-cadeias é igual ao comprimento da maior cadeia.

### 5.11 Fast Fourier Transform - FFT

```

   convolution(a, b, res);
   res = vector<T>(res.begin()+n, res.begin()+(2*n));
}
```

# Capítulo 6

# Processamento de Strings

### 6.1 Aho-Corasick

Após inserir todas as strings, chamar a função aho();

```
#define MAXN 100100
#define ALPHA 15
{f int} trie [MAXN] [ALPHA];
int term [MAXN];
int failure [MAXN];
int cnt;
void insert(string s){
    int node = 0;
    for (auto c : s) {
        if (! trie [node] [c-'a'])
        trie[node][c-',a'] = cnt++;
        node = trie[node][c-'a'];
    term[node] = 1;
}
void aho(){
    queue < int > q;
    \quad \textbf{for} \, (\, \textbf{int} \quad i \ = \ 0 \, ; \quad i \ < \, \text{ALPHA} \, ; \quad i + +) \{ \quad
        if(trie[0][i]){
            failure[trie[0][i]] = 0;
            q.push(trie[0][i]);
    while(!q.empty()){
```

### int u = q.front(); q.pop();for (int i = 0; i < ALPHA; i++){ ${\bf i}\,{\bf f}\,(\;t\;r\,i\,e\;[\,u\,]\,[\;i\;]\,)\;\{$ int v = failure[u]while (v && !trie[v][i]) v = failure[v];v = trie[v][i];failure[trie[u][i]] = v;term[trie[u][i]] = term[v];q.push(trie[u][i]); } } } int next(int node, int c){ while(node && !trie[node][c]) node = failure[node]; return trie[node][c]; void init(){ memset(trie, 0, sizeof trie); $memset \, (\, t\, erm \; , \quad 0 \; , \quad \textbf{sizeof} \quad t\, erm \, ) \; ;$ memset(failure, 0, sizeof failure); memset(vis, 0, sizeof vis); cnt = 1;

# 6.2 Rabin-Karp

String matching O(|S| + |T|).

```
string s, t; // input
const int p = 31;
vector<ull> p_pow(max(s.size(), t.size()));
p_pow[0] = 1;
for(int i = 1; i < p_pow.size(); i++)
    p_pow[i] = p_pow[i-1]*p;

vector<ull> h(t.size());
for(int i = 0; i < t.size(); i++){
    h[i] = (t[i]-'a'+1) * p_pow[i];
    if(i)
        h[i] += h[i-1];</pre>
```

```
| }
| ull h_s = 0;
| for (int i = 0; i < s.size(); i++)
| h_s += (s[i]-'a'+1) * p_pow[i];
| for (int i = 0; i + s.size()-1 < t.size(); i++){
| ull cur_h = h[i+s.size()-1];
| if(i)
| cur_h -= h[i-1];
| if(cur_h == h_s * p_pow[i])
| cout << i << """;
| }
| </pre>
```

### 6.3 Repetend: menor período de uma string

Menor período de uma string em O(n).

## 6.4 Suffix Array

### 8.2 Hash C++11

```
hash<string> hashFunc;
cout << hashFunc("Gabriel") << endl;</pre>
```

#### 8.3 Mo's

Cada query em O(sqrt(N)).

```
#define MAXN 100100
int BLOCK; // ~sqrt (MAXN)

struct query {
  int l, r, id;
  bool operator < (const query foo) const {
   if (l / BLOCK != foo.l / BLOCK)
      return l / BLOCK < foo.l / BLOCK;
  return r < foo.r;</pre>
```

```
};
int vis[MAXN], resp;

void add(int id){
   if(!vis[id]){
      // Add element and update resp
}
else{
```

```
// Remove element and update resp
                                                                              for(int i = 0; i < q; i++){
    vis[id] ^= 1;
                                                                                  int l = queries[i].l, r = queries[i].r;
}
                                                                                   while (curL < 1)
                                                                                                           add(curL++);
// IN MAIN
                                                                                   while (curL > 1) add(-curL);
                                                                                   \mathbf{while}\,(\,\mathrm{curR}\,<=\,\mathrm{r}\,)\ \mathrm{add}\,(\,\mathrm{curR}++)\,;
int q;
sort(queries, queries+q);
                                                                                   while (curR > r+1) add(--curR);
\mathbf{int} \ \mathrm{ans} \left[ \right. q \left. \right];
                                                                                   ans[queries[i].id] = resp;
\mathbf{int} \ \mathtt{curL} \ = \ 0 \, , \ \mathtt{curR} \ = \ 0 \, ;
resp = 0;
```

### 8.4 Problema do histograma

Maior retângulo do histograma em O(n).

```
tp = s.top();
ll histograma(ll vet[], int n){
                                                                                  s.pop();
   stack < ll > s;
                                                                                  cur = vet[tp]*(s.empty() ? i : i - s.top
   l\, l \ ans \ = \ 0 \; , \ t\, p \; , \ c\, u\, r \; ;
                                                                                      () - 1);
   \quad \textbf{int} \quad i \ = \ 0 \, ; \quad
                                                                                  if (ans < cur)
   while(i < n | | !s.empty()){
                                                                                      ans = cur;
       if(i < n \&\& (s.empty() || vet[s.top()] <=
            v et [ i ] ) )
           s.push(i++);
                                                                          return ans;
        else {
```

## 8.5 Sliding Window - Mediana

Mediana de todas as janelas de tamanho K de um array O(nlog).

```
if (i == nums.size())
int k;
                                                                                   break;
vector < int > nums;
multiset < int > window(nums.begin(), nums.begin() +
                                                                               window.insert(nums[i]);
                                                                               if (nums[i] < *mid)
     k);
                                                                                   mid - -:
auto mid = next(window.begin(), k / 2);
\quad \textbf{for} \quad (\, \textbf{int} \quad i \!=\! k \; ; \quad ; \quad i \!+\!+) \quad \{ \quad
                                                                               if (nums[i-k] \ll *mid)
    int janela = (int)((double(*mid) + *prev(mid, 1))
                                                                                   mid++:
           - \ k\%2)) \ / \ 2) \ ; \ // \ \mathit{Tratando} \ \mathit{par} \ \mathit{e} \ \mathit{impar}
                                                                               window.erase(window.lower bound(nums[i-k]));
```
